

## CONTENTS

<b>Preface</b>	xi
<b>1 Introduction</b>	1
A review of the origins of entropy and classical thermodynamics, followed by a summary of 19th century attempts to explain these theories in terms of the underlying molecular constituents of macroscopic physical systems.	
1.1 Heat	1
1.2 The emergence of entropy	3
1.3 Classical thermodynamics	5
1.4 Is there a deeper interpretation?	9
<b>2 Some clarification from another direction</b>	15
The origins of modern information theory are reviewed, along with the early links with physics.	
2.1 Information and physics	18
<b>3 The probability connection</b>	21
A brief introduction to probability as logic, and development of the principle of maximum entropy as principally an algorithm of probability theory for the construction of prior probabilities in the presence of very general forms of information.	
3.1 The principle of maximum entropy	26
<b>4 Equilibrium statistical mechanics and thermodynamics</b>	34
An application of the theoretical tools developed in Chapter 3 to macroscopic systems in thermal equilibrium, wherein the Gibbs variational principle is understood as defining the equilibrium state.	
4.1 The meaning of maximum entropy	43
4.2 Fluctuations	51
4.3 A mischaracterization	55
<b>5 The presumed extensivity of entropy</b>	59
The requirement that entropy be an extensive function of extensive variables is examined in some detail, along with the possible connection to the indistinguishability of elementary particles.	

<b>6 Nonequilibrium states</b>	69
The first extension of the maximum entropy principle to nonequilibrium states is made here, with applications to inhomogeneous systems. An initial contact with linear transport processes in simple fluids is also included.	
6.1 The linear approximation	72
6.2 Simple fluids	75
6.3 A transport example	79
6.4 Inhomogeneous systems	81
6.5 Some reflection	87
<b>7 Steady-state processes</b>	89
Application to nonequilibrium stationary processes is made at this stage, with a focus on simple fluids.	
7.1 Steady-state transport processes in simple fluids	93
<b>8 Sources and time-dependent processes</b>	99
A careful analysis of time evolution in macroscopic systems is carried out, along with a critique of the standard equation of motion for the density matrix. The practical difference between microscopic and macroscopic equations of motion and the necessary relation to external sources is recognized explicitly.	
8.1 Equation of motion revisited	104
<b>9 Thermal driving</b>	107
The concept of thermal driving is introduced, wherein very general external sources going beyond simple mechanical and electrical forces are envisioned, from baseball bats to Bunsen burners. Elements of nonequilibrium thermodynamics are presented.	
9.1 Nonequilibrium thermodynamics	112
9.2 Linear heating	115
9.3 A special case: linear dynamic response	119
<b>10 Application to fluid dynamics</b>	124
An interlude in which the previous theoretical developments are applied to the fluid dynamics of simple fluids and the derivation of their macroscopic equations of motion from statistical mechanics.	
10.1 Hydrodynamic fluctuations	126
10.2 Fluid dynamics equations of motion	128
10.3 The onset of turbulence	132

10.4 Ultrasonic propagation	135
10.5 Correlations in nonequilibrium fluids	138
<b>11 Irreversibility, relaxation, and the approach to equilibrium</b>	142
Finally, the deep questions of the relation of entropy to these topics first raised in Chapter 1 are addressed and resolved satisfactorily.	
11.1 Irreversibility	143
11.2 The second law	148
11.3 Is time asymmetry an issue?	150
11.4 Relaxation and the approach to equilibrium	152
<b>12 Entropy production and dissipation rates</b>	160
The story concludes with a discussion of topics of current research interest, with an emphasis on exposing various myths in the folklore.	
12.1 The statistical mechanics formulation	167
<b>Appendix A Perturbation theory</b>	174
A mathematical exposition of the equations required to describe small departures from equilibrium.	
A.1 Fluid equations of motion	178
A.2 Operator identities	179
<b>Appendix B Dissipative currents and Galilean invariance</b>	181
Microscopic expressions for dissipative currents in simple fluids are exhibited, and the Galilean invariance of statistical mechanics is discussed in some detail.	
B.1 Galilean invariance	184
<b>Appendix C Analytic continuation of covariance functions</b>	189
A brief discussion of how the covariance or correlation functions are analytically continued into the complex plane so as to readily analyze their causal and dissipative properties.
